SOURCES AND CONCENTRATIONS OF CUPRIC FUNGICIDES FOR THE 1 CONTROL OF CITRUS BLACK SPOT¹ 2

3			_
4			[
5	ABSTRACT - Citrus black spot (CBS) is a severe disease for citriculture in the São Paulo		ve de
6	State, Brazil. Part of its management is focused on chemical control using cupric fungicides	l	e
7	and strobilurins. The objective of the present work was to evaluate the efficacy of three		
8	sources and three concentrations of cupric fungicides (copper hydroxide, copper oxychloride		
9	and cuprous oxide). Orange fruits of the Pera cultivar were bagged in the plants and the		
10	treatment with cupric fungicide was applied. The fruits were inoculated (by spray) with		
11	<i>Phyllosticta citricarpa</i> $(1 \times 10^4 \text{ conidia mL}^{-1})$ after 0, 7, 14, 21, and 28 days, and bagged again.		
12	The evaluation of incidence and severity was did at the harvest time of fruits. A second		
13	experiment was conducted under natural infection with the same treatments, consisting of		
14	application of fungicides at the stages F1 (petal fall) and F2 (fruits with diameter of 1 cm),		
15	using mechanized sprayer with mean flow of 7.35 L solution plant ⁻¹ . Subsequently, all		
16	treatments received four applications of azoxystrobin (30 g ha ⁻¹), plus mineral oil at 0.25%.		
17	Four monthly evaluations were done to determine the CBS incidence and severity. The initial		
18	applications with cupric fungicides are essential for the control of CBS; the fungicide copper		
19	hydroxide showed the best control of CBS with the lowest rate of metallic copper (43.7 g of		
20	Cu^{++} 100 L ⁻¹) in both experiments, regardless of the conduction conditions.		[

1

cuproso). Frutos de laranjeira 'Pera' foram ensacados nas plantas seguido de tratamento com 33 fungicida cúprico. Posteriormente, após zero; sete; 14; 21 e 28 dias tais frutos foram 34

inoculados com Phyllosticta citricarpa (1x104 conídios mL-1), por pulverização, seguido de 35 novo ensacamento. A avaliação da incidência e severidade da doença ocorreu na colheita dos 36 frutos. Um segundo experimento, sob infecção natural, foi constituído pelos mesmos 37 tratamentos, sendo os fungicidas aplicados nos estádios F1 (queda de pétalas) e F2 (frutos 38 39 com 1cm de diâmetro) mediante pulverização tratorizada e vazão média 7,35 L calda planta-1. 40 Subsequentemente, e de forma semelhante para todos os tratamentos, foram realizadas quatro aplicações de azoxistrobina (30 g de i.a./ha) acrescida de óleo mineral a 0,25%. Foram 41 realizadas quatro avaliações mensais para determinação da incidência e severidade dos 42 43 sintomas. Concluiu-se que: as pulverizações iniciais com fungicidas cúpricos são 44 fundamentais para o controle da mancha preta dos citros; independente das condições de 45 condução, para ambos os ensaios o fungicida hidróxido de cobre propiciou a melhor resposta de controle da mancha preta dos citros com a menor dosagem de cobre metálico (43,7 g de 46 Cu++100L-1). 47

52 INTRODUCTION

53

Citrus black spot (CBS) is caused by the fungus *Phyllosticta citricarpa* McAlp.
(teleomorph: *Guignardia citricarpa* Kiely) (BALDASSARI; WICKERT; GOES, 2008), and
is associated with citrus plants in several countries in Africa, Asia, Oceania (KOTZÉ, 2000;
EPPO, 2017), South America and North America, and in Caribe (TIMMER et al., 2000;
SCHUBERT et al., 2010; HIDALGO and PÉREZ, 2010). All citrus varieties of economic
importance are susceptible to this fungus, with losses that can reach 40% of the production
(SILVA JÚNIOR et al., 2016).

Palavras-chave: Citrus sinensis. Phyllosticta citricarpa. Cobre metálico.

The control of CBS is done usually by using fungicides; in Brazil, it is controlled mainly with use of cupric and strobilurin fungicides (MOTTA, 2009; VINHAS, 2011; SILVA JÚNIOR et al., 2016). Cupric fungicides are commonly applied after petal fall, corresponding to the stages F1 and F2, until the fruits reach diameter of 1 cm (STOLLER, 2010;), followed by two to five applications of strobilurin fungicides (SCALLOPPI et al., 2012), covering the more susceptible period for fruits (AGUIAR et al., 2012), from petal fall until the end of the summer, when rainfall periods of more than 8 hours still occur. Ikeda (2011) reported

satisfactory responses of control of CBS to the use of five or six applications of cupricfungicides combined or alternated with strobilurins.

70 Cupric fungicides are approved, for citrus plants, only for the control of citrus scab and melanosis, except copper hydroxide (Kocide WDG Bioactive, Mitsui & Co. Brasil, S.A.) 71 72 (MAPA, 2017); however, they are used isolate or in combination with strobilurins for the control of P. citricarpa (VINHAS, 2011). These fungicides are applied with four-week 73 intervals, beginning after ³/₄ of petals felled, and subsequently with 28-day intervals, 74 75 combined with application of strobilurins at 35-day to 42-day intervals (MOTTA, 2009). The recommended rates of cupric fungicides are 0.75 to 1.25 g L^{-1} for copper hydroxide, 2.5 g L^{-1} 76 77 for copper oxychloride, and 1.0 g L⁻¹ for cuprous oxide (MAPA, 2017). However, the rates used at the stages F1 and F2, and in subsequent applications in combination with strobilurins 78 79 for the control of CBS under field conditions vary, and are usually based on the fungicide 80 metallic copper contents. These recommendations are from studies with copper oxychloride; no studies comparing sources and concentrations of cupric fungicides are found. 81

In this context, the objective of the present work was to evaluate the efficacy of three sources and three concentrations of cupric fungicides under artificial conditions of inoculation with *P. citricarpa*, and under natural conditions, to determine the equivalence between the different compounds in relation to metallic copper concentration in the solution.

89

88 MATERIAL AND METHODS

90 Experiment I – Protector effect for different sources and rates of cupric fungicides
91 against *Phyllosticta citricapa* infection in orange fruits of the Pera cultivar

92 93

94

The experiment was conducted in 2012 in an orchard with orange plants of the Pera cultivar (plant spacing of 5.5×2 m), at a private property in Olímpia, state of São Paulo (SP),

95 Brazil (20°41'57.23"S and 48°59'35.33"W).

The isolated pathogen was from Conchal, SP, Brazil. It was multiplied in Petri dishes containing BDA medium and maintained in BOD at temperature of 25°C.

98 The fungicides evaluated were copper hydroxide (Kocide WDG Bioactive[®] 462 g of 99 copper hydroxide, Mitsui & Co. Brasil, S.A.), copper oxychloride (Recop[®] 840 g of copper 100 oxychloride, Atanor do Brasil), and cuprous oxide (Redshield 750[®] 750 g of cuprous oxide, [RC10] Comentário: Não pode separar este tópico.

101 Agrovant Comércio de Produtos Agrícolas Ltda). The treatments and rates used are shown in102 Table 1.

Approximately 5,000 fruits at stage F2 (STOLLER, 2010) of 100 plants were bagged on 103 104 02/23/2015 to avoid infections by P. citricarpa naturally presents in the area. When the plants were at stage F4, they were treated with cupric fungicide on 05/13/2016. Subsequently, the 105 fruits were inoculated with P. citricarpa $(1 \times 10^4 \text{ conidia mL}^{-1})$ in intervals of 0, 7, 14, 21, and 106 107 28 days. The inoculum was prepared and the inoculation was done according to the 108 methodology described by Almeida et al. (2008). After inoculation, the fruits were bagged again, using double layer bags (crystal paper), according to the methodology adopted by 109 110 Motta (2009). The fruits were kept in the bag until the harvest (10/31/2016).

111

112 **Table 1**. Description of the cupric fungicide treatments for the control of citrus black spot in

orange plants of the Pera cultivar, and their active ingredient concentrations, formulatedproduct rates, and metallic copper equivalent rates.

	Concentration	Rate per 100 liters of solution		
Treatments		Formulated	Metallic	
	g kg ⁻¹	Product	Copper	
Copper hydroxide (538 g kg ⁻¹)	538	125.0	43.7	
Copper hydroxide (538 g kg ⁻¹)	538	100.0	35.0	
Copper hydroxide (538 g kg ⁻¹)	538	75.0	26.2	
Copper oxychloride (840 g kg ⁻¹)	840	200.0	100.8	
Copper oxychloride (840 g kg ⁻¹)	840	180.0	90.7	
Copper oxychloride (840 g kg ⁻¹)	840	135.0	68.0	
Cuprous oxide (860 g kg ⁻¹)	860	120.0	90.0	
Cuprous oxide (860 g kg ⁻¹)	860	75.0	56.3	
Cuprous oxide (860 g kg ⁻¹)	860	56.3	42.2

115 Copper hydroxide = Kocide WDG Bioactive[®], Mitsui & Co. Brasil, S.A.; Copper oxychloride

116 = $\text{Recop}^{\text{(B)}}$, Atanor do Brasil; and Cuprous oxide = Redshield 750^(B), Agrovant Comércio de

117 Produtos Agrícolas Ltda.

119 The fungicides were applied according to an adaption of the method of Motta (2009); 120 fruits with diameter of 40 to 50 mm were individually sprayed with fungicide, plus mineral oil 121 at 0.20% ($v v^{-1}$).

122 A completely randomized experimental design was used, with a $3\times3\times5$ factorial 123 arrangement consisted of three fungicides, three rates, and 5 inoculation times, with four 124 replications. The plots consisted of 20 fruits. The control treatment consisted of fruits without 125 application of cupric fungicide and with artificial inoculation with *P. citricarpa*.

The evaluations consisted of determination of the incidence (%) of symptomatic fruits for citrus black spot (CBS), and the disease severity. The CBS severity was estimated using a scale of grades, according to visual symptoms in percentage of lesion area—0 = fruits without visual symptoms, 1= up to 0.8%, 2 = 0.8% to 1.6%, 3 = 1.6% to 3.1%, 4 = 3.1% to 6.2%, 5 = 6.2% to 12.5%, 6 = more than 6.2% (SPÓSITO et al., 2004).

The grades attributed to fruits were used to determine the disease index (DI), accordingto Wheeler (1969):

$$DI = \frac{1}{N} \sum_{i=0}^{m} i \cdot n_i$$

133 were *N* is the number of total fruits evaluated, *i* is the grade of the fruit, *ni* is the number of 134 fruits with grade *I*, and *m* is the maximum grade.

The grades attributed, disease index, and the other parameters were subjected to analysis of variance, and the means were compared by the Scott-Knott test at 5% probability of error.

138

Experiment II - Evaluation of rates of cupric fungicides for the control of citrus black spot

141

The experiment was conducted in 2007, under natural conditions of infection by *P*. *citricarpa*, in an orchard with orange plants of the Pera cultivar (]plant spacing of 7×3.5 m), at a private property of commercial production in Olímpia, SP, Brazil (20°47'59.17"S, 49°2'34.94"W).

146 The treatments evaluated in this experiment, representing the cupric fungicide 147 variations, were the same used in Experiment I (Table 1).

The fungicides were applied using a mechanized sprayer (FM Copling) with 54 nozzles
MagnoJet-DDC4, diffusers 25 with 758.42 kPa at 540 RPM, power takeoff with 1900 RPM,

and tractor speed of 3.4 km h⁻¹. The mean flowrate was 7.35 L plant⁻¹, equivalent to 134 mL m⁻³ on the plants' canopies. The cupric fungicides were sprayed when the plants were at the stages F1 and F2 (STOLLER, 2010), on 12/02/2015 and 12/23/2015. The spraying of fungicides were resumed on 01/13/2016 with foliar applications of 500 g of azoxystrobin (Vantigo[®], Syngenta Proteção de Cultivos Ltda, São Paulo) at concentration of 16 g per 100 L of water plus mineral oil (Agefix[®], Packblend Indústria e Comércio de Lubrificantes Ltda) at 0.25% (v v⁻¹) until 05/19/2016, totaling four applications with 42-day intervals.

A randomized block experimental design was used, consisting of 10 treatments and four
 replications. The plots consisted of three rows of 11 plants, totaling 33 plants or 808.5 m².

The evaluations were carried out on 08/10/2016, 09/08/2016, 10/06/2016, and 11/14/2016 to determine the CBS incidence and severity in 100 random fruits collected from the five central plants of each plot. The CBS severity was estimated using a scale of grades (SPÓSITO et al., 2004), and the data were used to determine the disease index (DI), according to the same equation used in Experiment I.

The DI data were used to determine the area under the disease progress curve (AUDPC) by the trapezoidal method (DI1 + DI2)/2*(Day2 - Day1). The fruits were harvested on 11/30/2016, when the fruit yield per plant (kg) was determined. The data were subjected to analysis of variance and the means were compared by the Scott-Knott test at 5% probability of error. The data were also subjected to regression analysis to determine the rates of each fungicide based on linear and quadratic responses of the AUDPC.

170 171

172 **RESULTS AND DISCUSSION**

173

174 Experiment I

175

All treatments with the highest rates of cupric fungicides presented on average lower incidence and severity of citrus black spot (CBS) (Table 2). The results showed direct and significant responses between fungicide rates and CBS incidence and severity, except for the treatment with copper oxychloride at 90.7 g 100 L⁻¹. However, high rates on equivalent metallic copper do not necessarily mean high concentrations of fungicide (SILVA JÚNIOR et al., 2016).

182 The number of days after the application of fungicides had a significant and negative 183 effect, with lower CBS incidence and severity when the inoculation with *Phyllosticta* [RC12] Comentário: Não pode separar este tópico.

citricarpa and the treatment was carried out on the same day. The inoculations between 7 and 28 days after the fungicide application resulted in similar protections. This result is related to those reported by Motta (2009), who found incidence of 30% and 80% when the inoculation was at 1 and 28 days after application of copper oxychloride, respectively. Thus, the methodology used is efficient to evaluate and replicate results, and can be used to evaluate new formulations or fungicides.

190 The interaction between the fungicide rates, fungicide sources, and days after treatment 191 of fruits was not significant, denoting that the protection tends to decrease over time at the same proportion for all the treatments, even when using different fungicide rates and sources. 192 193 These results showed that the best interval between applications of cupric fungicides depends on the control level desired, in terms of CBS incidence and severity. Thus, it can be weekly 194 195 for production of fruits with lower incidence, and up to 28 days for production of fruits with incidence and severity within limits that avoid the fall of fruits. Motta (2009) found similar 196 197 results, with increases in CBS incidence and severity as a function of increases in the intervals 198 between the application of copper oxychloride and artificial inoculation with P. citricarpa; 199 they reported satisfactory protection up to 21 days after the application.

200

201 Table 2. Incidence and disease index of citrus black spot (Phyllosticta citricarpa) in orange

202 fruits of the Pera cultivar as a function of cupric fungicides rates and sources and days after

the application, in the 2015/2016 crop season.

The data of incidence and severity of citrus black spot were transformed according to the equations $x' = arcsen\sqrt{x/100}$, and $x' = \sqrt{x + 0.5}$, respectively. Means followed by the same letter in the columns do not differ by the Scott-Knott test at 5% probability of error. ** = significant by the analysis of variance at 1% probability of error; ns = not significant by the analysis of variance at 5% probability of error.

209

210 Experiment II

211

212 According to the first evaluations, in August, the highest cupric fungicide rates were significantly more efficient to reduce the CBS incidence (Table 3). However, they did not 213 214 necessarily represent the same metallic copper rate (Table 1), contradicting the 215 recommendation by equivalence (SILVA JÚNIOR et al., 2016b). These data showed that the 216 rate should be specific for each cupric fungicide source, and cannot be generalized or equalized by the equivalent metallic copper. These differences were less pronounced over the 217 218 evaluations, although a high effectiveness had been maintained. The CBS incidence in the control treatment varied from 44% to 94% from the first (10/08) to the last evaluation (14/11), 219 220 while in the most efficient chemical treatment it varied from 28% to 77%. These are similar 221 results to those found by Scalloppi et al. (2012), who found that better responses are 222 dependent on the simultaneous use of different alternatives, including fungicide with different properties from protectors and cultural practices that reduce the inoculum, thus, reducing theCBS incidence and severity.

225

233

The treatments had no effect on the CBS severity (Table 4); the CBS severity increased even in plots treated with fungicide. No treatment completely controlled the CBS. The fungicides and rates presented no differences for the control of CBS; they were different only from the control treatment.

Table 4. Severity of citrus black spot (*Phyllosticta citricarpa*) in orange fruits of the Pera
cultivar treated with different cupric fungicides rates and sources in the 2015/2016 crop
season.

The data of severity of citrus black spot were transformed according to the equation $x' = \sqrt{x/0.5}$. Means followed by the same letter in the columns do not differ by the Scott-Knott test at 5% probability of error. ** = significant by the analysis of variance at 1% probability of error.

246 247

The initial cupric fungicide applications by spraying were essential to control CBS, since the control treatment without application of cupric fungicides presented higher CBS incidence and severity (Table 5).

According to the area under the disease progress curve (AUDPC) for CBS incidence, only the lowest rates of copper oxychloride (135 g 100 L⁻¹) and cuprous oxide (75 g 100 L⁻¹) presented significant lower efficiency, increasing the CBS incidence (Table 5). The AUDPC for CBS severity showed that all the treatments were significantly different, and that they were different from the control treatment. Regarding the copper hydroxide, only the highest rate (125 g 100 L⁻¹) was equivalent to the best treatments; the intermediate and highest rates of copper oxychloride and cuprous oxide presented the best results of control.

258

Table 5. Area under the disease progress curve (AUDPC) for incidence and severity of citrus
black spot (*Phyllosticta citricarpa*) and yield of orange plants of the Pera cultivar as a
function of cupric fungicides rates and sources, in the 2015/2016 crop season.

The data of incidence and severity of citrus black spot were transformed according to the equations $x' = arcsen\sqrt{x/100}$, and $x' = \sqrt{x + 0.5}$, respectively. Means followed by the same letter in the columns do not differ by the Scott-Knott test at 5% probability of error. ** e significant by the analysis of variance at 1% probability of error; ns = not significant by the analysis of variance at 5% probability of error.

267

As in Experiment I, the results of Experiment II showed no equivalence in metallic copper rate in the treatments with the best control of CBS. The treatment 1 (copper hydroxide at 125 g 100 L⁻¹) had the lower metallic copper concentration in the solution (43.7 g 100 L⁻¹). When using 42.2 g 100 L⁻¹ with cuprous oxide, the results were significantly lower. These were similar results to those found by Feichtenberger et al. (2001), who found equivalence of control between cupric fungicides using a high rate of metallic copper (90 g of Cu⁺⁺ 100 L⁻¹).

The orange yield presented no significant differences (Table 5). The sequence of the experiment with applications of azoxystrobin maintained the CBS severity at lower levels in the control treatment, presenting no yield losses, but losses in the fruit aesthetical quality, which were not suited for marketing as fresh fruits.

Significant linear responses of the CBS were found for all fungicide treatments, indicating that the better control levels of CBS are achieved with the use of increasing rates of Cu^{++} (Table 6 and Figure 1). However, this result makes unfeasible the determination of the threshold for control of CBS and maximum fungicide rate, within the range of ratesestablished for this experiment.

A = Copper hydroxide; B = Copper oxychloride; C = cuprous oxide

Figure 1. Graph of the linear regression model for the area under the disease progress curve (AUDPC) for citrus black spot (*Phyllosticta citricarpa*) in orange of the Pera cultivar, for each cupric fungicide as a function of the metal rate copper used, in the 2015/2016 crop season.

293

294

295 CONCLUSION

296

The fungicides copper hydroxide, copper oxychloride, and cuprous oxide at rates of 43.7, 90.7, and 56.3 g of Cu^{++} 100 L^{-1} , respectively, are efficient and present similar results for the control of citrus black spot when applied with 21-day intervals and before applications of strobilurin fungicides.

The fungicides copper hydroxide, copper oxychloride, and cuprous oxide at rates of 43.7, 90.7 and 90 g of Cu^{++} 100 L⁻¹, respectively, can control protectively citrus fruits from infections with *Phyllosticta citricarpa* up to 28 days.
